Aim

The purpose of this trial was to carry out an invitro study of Psa survival in wound protectant (PruneTec).

Background

Wound protectants are used to protect wounds following pruning and grafting. Kiwifruit vines are pruned to remove excess wood in summer and to structure the vine in winter. Pruning wound dressings generally contain a bactericide that aimed at providing protection from bacterial infections. This report presents the evaluation of PruneTec 20001948 wound protectant tested against Psavo to determine efficacy under laboratory conditions.

The products were tested to determine
1) its minimum inhibitory concentration (MIC)
2) Survival of Psavo in protectant (Kill rate v/s time)
3) Quantification and repeatability

Table 1 below shows the list of products tested and the main active ingredients.

Methodology

1. Agar susceptibility

A standard petri dish containing Mueller-Hinton CLSI agar was used for product testing. A 12 mm core of agar was excised from the surface of the plate. 30μL aliquots of the product (neat) were introduced into the excised holes and allowed to diffuse for 10 minutes before Psa was applied. An inoculum of Psa was prepared in sterile distilled water to a concentration of 0.5 McFarland Standard. This was evenly spread over the entire surface of the plate using a swab. The inoculated plate was incubated at 25 ± 2 °C for 48 hours and examined for signs of antimicrobial activity.
2. **Minimum Inhibitory Concentration (MIC) in sterile distilled water**

This assay measures the activity of the product against a target bacterium. For the Minimum Inhibitory Concentration (MIC), the product was tested at ten different concentrations; 0.1%, 0.5%, 1%, 2%, 5%, 10%, 20%, 50%, 70% and 90% which were prepared in Psa suspension of known concentration- ranging between $10^7$ and $10^8$ cfu/mL. The tubes were incubated at 25 ± 2°C for 48 hours. The minimum bactericidal concentration (MBC) of the product was determined by sub-culturing the contents of the tubes on Aitken media and blood agar. The plates were then incubated at 25 ± 2°C for 48 hours and examined for signs of antimicrobial activity. Based on the results obtained in the dilution test, a working concentration of each product was determined.

3. **Determination of Psa-V survival after inoculation of product (kill rate v/s time)**

Once the minimum inhibitory concentration (MIC) was determined, the survival of Psa-V was conducted by inoculating the product with Psa followed by incubation at 25°C. The products were tested after incubation times of 15 minutes, 30 minutes, 1 hour, 3 hours and 7 hours following inoculation. At each time interval, the inoculated product was streaked to determine the kill rate versus time and a growth score was recorded. A set of controls were also conducted with only Psa solution and no product at each time interval.

4. **Quantification and repeatability**

Once, the window of concentration of product versus kill rate versus time was determined, the time was further narrowed. The Psa solution was quantified pre-use by serial dilution and plating on Aitken media and run in sets of 5 replicates. A positive control was set with only Psa-V solution. At the end of incubation, the 5 replicates were quantified by serial dilution and plating and plates were read 48 hours post incubation.

**Results**

1. **Agar Susceptibility**

2. Minimum Inhibitory Concentration (MIC) in sterile distilled water

The minimum inhibitory concentration of the product tested from 0.1 % to 90% dilution is shown in Table 3. A range of concentrations where both growth and no-growth of Psa-V was obtained and a working concentration for the product, derived from the MIC was used for subsequent testing. PruneTec 20001948 showed efficacy against Psa-V at or greater than 5 %.

2. Determination of Psa-V survival after inoculation of product.

Since the wound protectants are generally used undiluted in the orchard, a working concentration of 50% and 70% were used instead of the minimum inhibitory concentration. Absolute kill was obtained within 1 hour incubation. The Psa-V solution used for this trial was at a high concentration of 1 x 10^8 cfu/mL.

3. Quantification and Repeatability

At 1 hour, Psa-V could not be isolated from PruneTec 20001948. Subsequent repeated testing indicated the same result. Refer to Table 5a.

Conclusions

PruneTec 20001948 showed absolute kill to Psa-V within an hour of incubation.

Product Testing Disclaimer

Verified Lab Services is a trading division of Seeka Kiwifruit Industries Ltd. Verified Lab Services and Seeka Kiwifruit Industries make no representation or guarantee as to the product tested and its effectiveness as a treatment for PSA. Results above may not be conclusive due to limitations of the testing method and limitations of the product. Limitations of the testing method include but are not limited to: inability to evaluate the efficacy of biological control agents, inability to demonstrate efficacy of products that cannot diffuse through agar or make broth cloudy, inability to demonstrate efficacy of plant elicitors.
